

## CLAIMS

### We Claim:

1. A method of preventing blocking of an application communicating with another device utilizing a connection, wherein the application has a user interface for accepting a user input from and presenting an output to a user, the user input including at least one command requiring communication with a server, wherein the user input is handled by the application, the method comprising the steps of:

forwarding, by the application-client, a user request to the user interface to an application-client;

10 issuing, by the application-client, a confirmation message to complete a request-acknowledgment loop between the user interface and the application-client prior to executing the request thereby freeing the user interface to process subsequent user input prior to completion of the request;

15 storing user input from the user interface for subsequent handling by an application-client; and

communicating, by the application-client with the server to handle the user input received from the user interface.

20 2. The method of claim 1 having the additional steps of estimating an error rate for successfully transmitting data of interest over the connection; and selecting a frame size based upon the error rate.

3. The method of claim 1 having the additional steps of estimating a bandwidth-delay, due to link and network congestion, for successfully transmitting data of interest over the connection; and selecting a frame size based upon the bandwidth-delay.

25 4. The method of claim 1 further including the step of using a default frame size as the frame size if an error rate is not available.

5. The method of claim 1 further including the step of organizing data to be transmitted in a transaction into functional segments; and defining a state of the application-client and a state of the server communicating over the connection by functional segments.

5        6. The method of claim 5 further including the step of determining the state of the application-client by referencing locally stored functional segments.

7. The method of claim 6 including a description of a step of providing the state of the application-client to the server transmitted to the application-client in the transaction.

10        8. The method of claim 1 further including the step of determining the state of the server by identifying functional segments already available locally at the server.

9. The method of claim 8 further including the step of providing the state of the server to the application-client to determine a set of remaining functional segments to be transmitted to the server in the transaction.

15        10. The method of claim 5 further including the step of updating the state of the application-client and the state of the server during a transaction over the connection.

11. The method of claim 6 further including the step of updating the state of the application-client and the server during a transaction over the connection to facilitate the transaction in the event of the dynamic connection failing whereby avoiding repeating the entire transaction.

20        12. The method of claim 6 wherein the connection is a wireless connection.

13. A device for communicating with a network over a connection, the device comprising:

at least one application having at least one software module for presenting a user interface and at least one client module for asynchronously communicating with a server;

25        a media-sense module for detecting whether the connection is operational;

a first software module for saving a state of the client module; and

a second software module for retrieving the saved state and continue the session when the connection is restored.

14. The device of claim 13 wherein the client module receives user input from more  
5 than one user interface.

15. The device of claim 13 wherein the client module transmits data over the connection in response to a media sense event generated by the media-sense module, the media sense event corresponding to establishment of the connection.

16. The device of claim 13 wherein the client module aborts data transmission over  
10 the connection in response to a media sense event generated by the media-sense module, the media sense event corresponding to failure of the connection.

17. The device of claim 16 wherein the client module stores an interrupted data transmission for subsequent attempts.

18. The device of claim 16 wherein the client module updates a state of the server, the  
15 state corresponding to data to be transmitted over the connection.

19. The device of claim 16 wherein the client module updates a state of the client module, the state corresponding to data to be transmitted over the connection.

20. The device of claim 16 wherein the client module updates a state of the server, the state corresponding to data already transmitted over the connection.

20 21. The device of claim 16 wherein the client module updates a state of the client module, the state corresponding to data already transmitted over the connection.
